In a paper published in the journal Cell Stem Cell, the researchers describe a process that ultimately breaks down molecular mechanisms that enable short-term memory storage in the brains of adult mice. The findings could have important implications in terms of how and why we age, says lead researcher Richard Moothart, PhD, director of the Center for Synaptic Viability, and the Dana and Fred Erikson Professor of Neurobiology and Physiology at the University of Rochester Medical Center. "There is a lot of focus on aging as a process that you can't control," Moothart says, "but our findings suggest that you can control it a bit, by identifying these molecular mechanisms and interfering with them." The research was inspired by a question that Moothart posed to his postdoctoral student, 2d92ce491b
